Case report
Simultaneous nasopharyngeal and parotid gland Warthin’s Tumour: a case report

Un caso raro di tumore di Warthin sincrono della ghiandola parotide e del rinofaringe

SUMMARY
Herein, a rare case of synchronous cystoadenolymphoma (Warthin’s tumour) of the right parotid gland and the nasopharyngeal space is described. Although Warthin’s tumour (WT) of the parotid gland is a common benign pathology, the occurrence of extra-parotid cystoadenolymphoma is rare. Extra-parotid WT have been mainly localized in the submandibular gland, periparotid region and occasionally in other sites, such as the oral cavity, hard palate and nasopharynx. The simultaneous occurrence of an intra-parotid and extra-parotid WT localization, as in the case presented, is extremely uncommon.

KEY WORDS: Warthin’s tumour • Parotid Gland • Nasopharynx

INTRODUCTION
Warthin’s tumour (WT) is a benign salivary gland tumour, almost exclusively located in the parotid gland and periparotid region1. From 12-19% of patients develop more than one WT, frequently with a bilateral parotid involvement (incidence: 5-14%)1. WT has been rarely reported to occur at multiple sites and at the same time; to the best of our knowledge, in the literature there is only another case report of a simultaneous intra-parotid and extra-parotid WT2.

Case report
A 63-year-old man was referred to the ENT department of the University Hospital of Ferrara for the assessment of a right, non-painful, parotid mass. The lesion had been present for 4-6 months, but was increasing in size very slowly. He was also complaining the onset of snoring since 6 months with occasional nasal discharge. Apart from a 40-year habit of smoking 20 cigarettes a day and the onset of a non-insulin dependent diabetes mellitus two years ago, his medical history was unremarkable.

ENT examination revealed a mobile 3.5 × 2.0 cm mass just behind the angle of the jaw (right side). Facial nerve function was normal. Nasopharyngeal endoscopy revealed an oval mass (1.0 cm) with a smooth surface in the left side of the nasopharynx. There were no other notable findings on physical examination. Fine needle aspiration of the right parotid mass was performed. Histological examination revealed mixed lymphoid cells (lymphocytes and macrophages). The exact anatomical location of both lesions was confirmed by MRI (Fig. 1A-B).

Under general anaesthesia, the parotid mass was excised, via a superficial parotidectomy; at the same time, the nasopharyngeal mass was removed under FESS guidance. At histological examination, a synchronous parotid and nasopharyngeal WT was diagnosed (Figs. 2, 3). There have been no signs of tumour recurrence at 16 months postoperatively.

Discussion
Warthin’s tumour (adenolymphoma, papillary cystadenomato- ma lymphomatous, cystoadenolymphoma) is one of the
most common benign salivary gland tumours, generally involving the parotid gland. Even if benign tumours of the salivary glands are more common in women, WT, on the other hand, is found more frequently in men between the ages of 55 and 70 years. An association with cigarette smoking has been described. Although some cases have been reported in extra-parotid locations such as the cervical lymph nodes, submandibular gland, lip, cheek, tongue and hard palate, WT of the nasopharynx are extremely rare. Only few isolated cases of primitive nasopharyngeal involvement have been described so far, and we could find (through a PubMed database search performed in January 2011) only one published case of a nasopharyngeal WT with a simultaneous associated parotid tumour. A synchronous intraparotid and extra-parotid WT, as in our case, can therefore be considered exceptional. Histologically, WT is an adenoma in which bilayered columnar and basaloid oncocytic epithelium forms multiple cysts with multiple papillae and accompanied by a proliferation of lymphoid tissue. Sometimes, oncocytic cells

Fig. 1. A. T1 weighted MRI scan, coronal section: a 3.5 × 2.0 cm mass is located in the superficial lobe of the right parotid gland. B. T1 weighted MRI scan, axial section: an oval mass of about 1.0 cm in diameter is located in the left side of the nasopharynx.

A case of simultaneous cystoadenolymphoma of nasopharynx and parotid
can also form in nodal tissue. Our case was judged to meet
these criteria and the lesion was diagnosed as WT.
It is difficult to explain the occurrence of a synchronous
intra-parotid and extra-parotid WT. To date, there is no
evidence in either the previously reported case 2 or our
patient that one or more systemic or local factors might
have influenced or induced the development of WT in two
different sites: the hypothesis that we can make is of a
multiple and simultaneous origin.
The origin of WT is still controversial and has been much
debated. The most accepted hypothesis suggests that
parotid WT could arise from salivary duct epithelium
inclusions in the parotid gland lymph nodes, during on-
togeny 2 11. Nonetheless, other authors propose that the
lymphocytic component is the result of an immunological
reaction to the epithelial component, or could arise as an
inflammatory response 23.
At the same time, the pathogenesis of nasopharyngeal WT
also remains unclear. By using monoclonal antibodies,
Fantozzi et al. found the ratio of T to B cells in extrapa-
rotideal WT to be similar to that of a normal lymph node,
thus strengthening the theory of salivary organogenesis
rather than that of reactive proliferation or hypersensitivity
12. Extraparotideal WT may then arise from components
of the minor salivary glands that are engaged in a pre-
existing lymphoid strroma, and chronic inflammation in
the nasopharynx could induce the formation of oncocytic
metaplasia of glandular tissues in the strroma 29.
The question also arises as to whether cigarette smoking,
a chronic inflammatory stimulus, as well as a reported risk
factor for the onset of WT 23, could have acted as a trigger
for the simultaneous occurrence of WT in this case.
In conclusion, WT is a predominantly benign lesion
almost exclusively found in the parotid, which can excep-
tionally appear simultaneously in other areas, such as the
nasopharynx. Head and neck surgeons should always be
aware of extra parotideal WT and consider performing
MRI in highly suspicious cases during initial workup.
Available data 2 6 support a surgical, conservative, ap-
proach to the management of WT, even in case of syn-
chronous lesions, as in the patient presented.
It is likely that once the details of the pathogenesis of WT
are better clarified, it will be possible to understand the
occurrence of synchronous and/or multifocal lesions.
